INDIA: CLEAN ENERGY FROM BIOMASS

Environmental problems in India are growing rapidly. The increasing economic development and a rapidly growing population that has taken the country from 300 million people in 1947 to more than one billion people today is putting a strain on the environment, infrastructure, and the country's natural resources.

India's air pollution is exacerbated by its heavy reliance on coal for power generation. Coal supplies more than half of the country's energy needs and is used for nearly three-quarters of electricity generation. While India is fortunate to have abundant reserves of coal to power economic development, the burning of this resource, especially given the high ash content of India's coal, has come at a cost in terms of public health risk and environmental degradation. Reliance on coal as the major energy source has led to a nine-fold jump in carbon emissions over the past forty years. The government estimates the cost of environmental degradation has been running at 4.5% of GDP in recent years.

SWITCHING FROM COAL TO RENEWABLE BIOMASS

Biomass projects are implemented in small or large industrial plants and aim at utilizing agricultural waste or other non-renewable biomass residues as fuel to generate power and lower their dependence on the local grid. Before the implementation of the project, electricity needs of such plants were met by power from the coal dominated grid. To meet the rising energy demands in production, they install a new efficient biomass boiler and a steam turbine, producing both steam and electricity. The new boilers are red with locally available agricultural waste instead of emission-intensive coal.

Key Facts:
- Location: India
- Project type: Renewable Energy: Biomass
- Project standard: VCS
Sustainability benefits
Beyond the reduction of greenhouse gases these projects contribute to local sustainable development by:

- Creating jobs in the construction, maintenance, and operation of the plant as well as in the biomass logistics
- Creating additional income for farmers from agricultural waste
- Alleviating the load on the regional electricity grid
- Reducing emissions of air pollutants from fossil fuel burning like SO2, soot and particulate matter
- Demonstrating and spreading renewable energy technology
- Creating a business case for regional empowerment through environmentally friendly technology
- By utilizing locally available, sustainable fuel sources thereby reducing the dependence on energy imports on a national level

Before the start of the project, these agricultural residues were not used. They were either burned without harnessing the resulting thermal energy, or simply left to decay, thereby generating methane emissions. The plant’s steam and electricity requirements can be now covered by the new cogeneration unit. The investment required for the installation of the new cogeneration unit could not have been raised were it not for the revenue of future sales of carbon credits.

TECHNOLOGY BRIEF – HOW IT WORKS
Biomass refers to biological material derived from organic matter such as wood and organic wastes. Biomass may be grown especially for the purpose of generating heat or power, but in the case of this project, the biomass is from locally available agricultural waste. The use of agricultural residues is particularly sensible because clean energy is sourced from materials that would otherwise have been left to decay, generating methane.
